

3D coordinates and basic transforms

Homogeneous coordinates

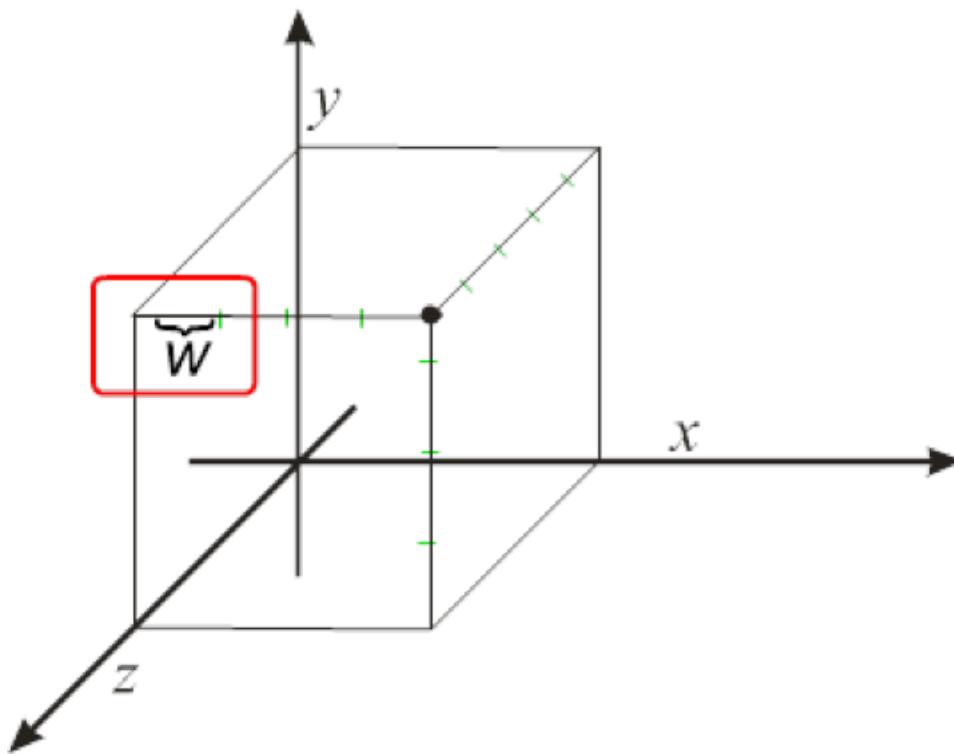

In order to represent objects in a 3D space, an appropriate coordinate system must be chosen.

For reasons that will be clear when we will deal with transformations and projections of 3D coordinates, a special system called *homogeneous coordinates* is used.

In homogeneous coordinates, a point in the 3D space is characterized by four values: x , y , z and w .

Homogeneous coordinates

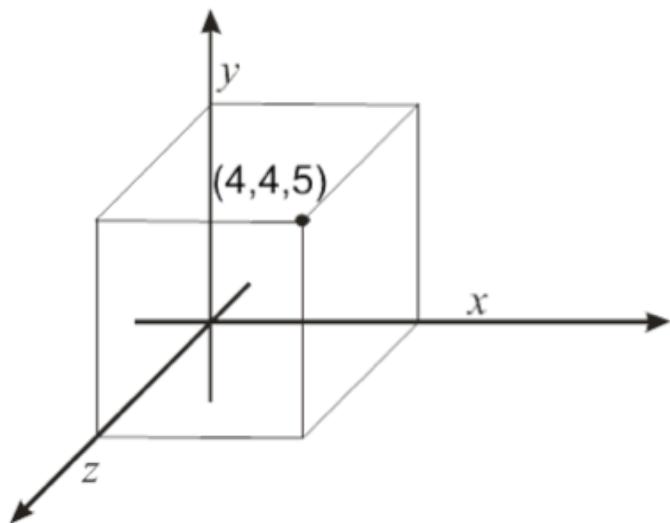

The coordinates x , y and z represents the position of the point in the 3D space, while coordinate w defines a *scale*: the units of measure used by the coordinates.

Homogeneous coordinates

Since we have four values to define a point in a 3D space, we have an infinite number of coordinates that identify the same position.

In particular *all tuples of four values that are linearly dependent* represents the same point in the 3D space.

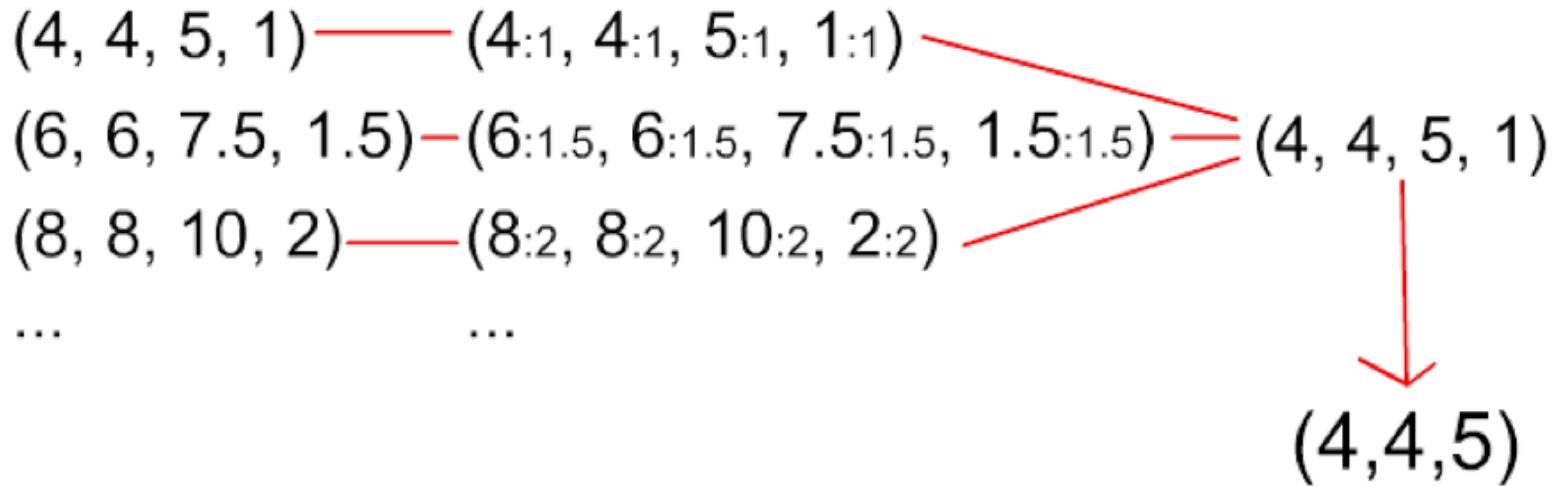

- (2, 2, 2.5, 0.5)
- (4, 4, 5, 1)
- (5, 5, 6.25, 1.25)
- (6, 6, 7.5, 1.5)
- (-8, -8, -10, -2)
-

Homogeneous coordinates

The x , y , and z coordinates of the vector with $w = 1$ identify the “real” position of the point in the 3D space.

Since all the vectors representing the same point are linearly dependent, we can obtain the one with $w = 1$ by simply dividing all the components by w .

Homogeneous coordinates

In other words we can find the (x',y',z') Cartesian coordinates corresponding to any point in homogeneous coordinates (x,y,z,w) by dividing the first three components by the last one.

$$(x, y, z, w) \rightarrow (x', y', z') = \left(\frac{x}{w}, \frac{y}{w}, \frac{z}{w} \right)$$

Conversely, we can simply transform a point with Cartesian coordinates (x,y,z) into homogeneous coordinates by adding a fourth component $w=1$.

$$(x, y, z) \rightarrow (x, y, z, 1)$$

Homogeneous coordinates

Example:

The Cartesian coordinate:

$$A_c(1, 3, -5)$$

corresponds in homogeneous coordinates to:

$$A_h = (1, 3, -5, 1)$$

The homogeneous coordinates:

$$B_h(1, 3, -5, 2), \quad C_h(6, -3, 2, 1/2)$$

in Cartesian coordinates correspond respectively to:

$$B_c = (1, 3, -5, 2) = (1/2, 3/2, -5/2) = (0.5, 1.5, -2.5)$$

$$C_c = (6, -3, 2, 1/2) = (6/0.5, -3/0.5, 2/0.5) = (12, -6, 4)$$

Affine transforms

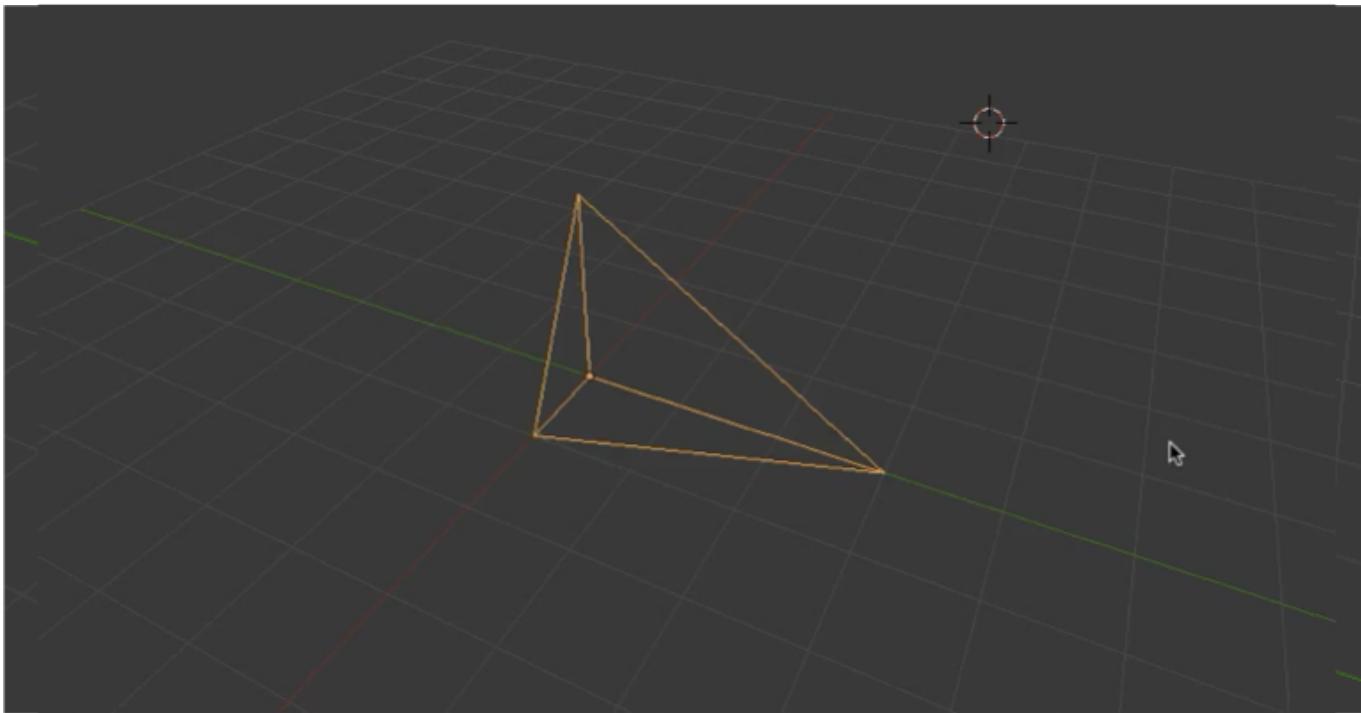

The process of varying the coordinates of the points of an object in the space is called **transformation**.

Transformation in 3D can be quite complex, since all the points of the object should be repositioned in a three-dimensional space.

However, there is an important and large set of transformations that can be summarized with a mathematical concept known as *affine transforms*.

Affine transforms

Objects are defined in the 3D space through the coordinates of their points.

By applying affine transformations to the coordinates of their points, objects can be moved, rotated or scaled in the space.

Affine transforms

The affine transforms are usually grouped in four classes:

- *Translation*
- *Scaling*
- *Rotation*
- *Shear*

To translate, rotate or scale an object, the same transformation is applied to all its points.

The transformed object is obtained by reconstructing the geometric primitive with the new points.

Affine transforms

In the following, we will call $p=(x,y,z,w)$ the original vertex, and with $p'=(x',y',z',w')$ the transformed vertex.

4x4 Matrix transforms

When using homogeneous coordinates, *4x4 matrices* can express the considered geometrical transforms.

The new vertex p' can be computed from the old point p by simply multiplying it with the corresponding transform matrix M .

The basic transformations we are considering, assumes and are constructed to maintain the fourth component of the resulting vector $w=1$.

$$p = (x, y, z, 1)$$

$$p' = M \cdot p^T$$

$$p' = (x', y', z', 1)$$

4x4 Matrix transformations

Note that two different conventions can be used:

- Transform Matrix on the left
- Transform Matrix on the right.

Matrix-on-the-left

$$p = (x, y, z, 1)$$

$$p' = (M \cdot p^T)^T$$

$$p' = (x', y', z', 1)$$

Matrix-on-the-right

$$p = (x, y, z, 1)$$

$$p' = p \cdot M^T$$

$$p' = (x', y', z', 1)$$

We will use the convention with the matrix-on-the-left, since it is the most used in text-books. We will also consider only column vectors, and drop the “ T ” operator in the matrix products.

Be careful however that many libraries used to ease the development of 3D applications adopt the matrix-on-the-right convention.

Identity transform

The simplest transform, is the one that does not perform any change on the points of an object.

This is the *Identity Transform*.

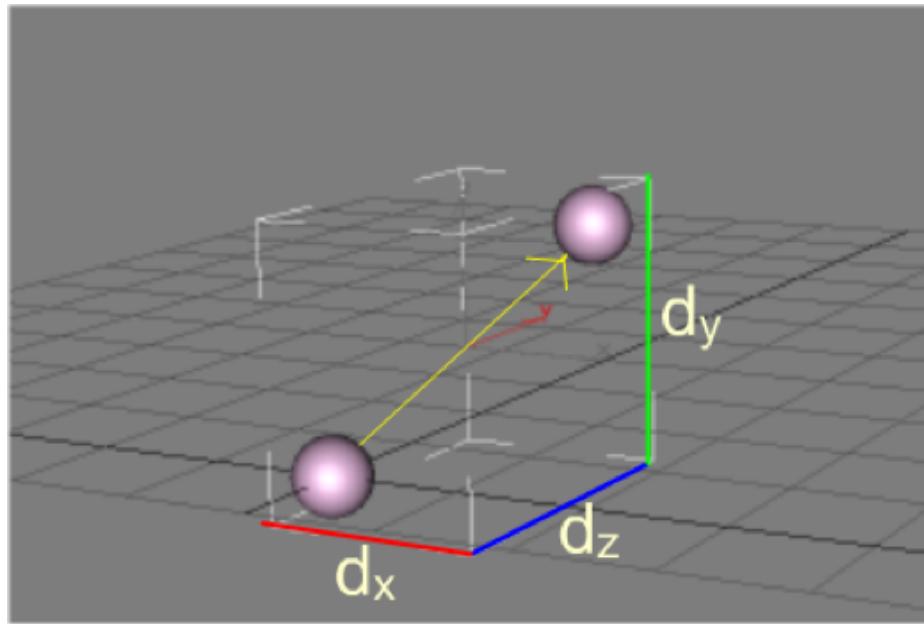

As the name suggests, it can be implemented with a 4x4 identity matrix.

$$I = \begin{vmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{vmatrix}$$

Translation

Translation moves the points of an object, while maintaining its size and orientation.

Let us imagine moving an object of d_x units along the x-axis, d_y on the y-axis and d_z on the z-axis.

Translation

The new coordinates can be obtained by simply adding the corresponding movement to each axis:

$$x' = x + d_x$$

$$y' = y + d_y$$

$$z' = z + d_z$$

Since in homogeneous coordinates the w component is always $w=1$, the translation matrix $T(d_x, d_y, d_z)$ can be obtained by putting d_x , d_y and d_z on the last column of an identity matrix.

$$T(d_x, d_y, d_z) = \begin{vmatrix} 1 & 0 & 0 & d_x \\ 0 & 1 & 0 & d_y \\ 0 & 0 & 1 & d_z \\ 0 & 0 & 0 & 1 \end{vmatrix}$$

Translation

Example:

Consider a translation of +2 on the x-axis and -2 on z-axis:

The corresponding matrix is $T(2,0,-2)$, and it can be used in the following way to transform points:

$A(1, 2, 3), B(-4, 2, -1)$.

$$T(2,0,-2) = \begin{vmatrix} 1 & 0 & 0 & 2 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & -2 \\ 0 & 0 & 0 & 1 \end{vmatrix}$$

$$A' = \begin{vmatrix} 1 & 0 & 0 & 2 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & -2 \\ 0 & 0 & 0 & 1 \end{vmatrix} \begin{vmatrix} 1 \\ 2 \\ 3 \\ 1 \end{vmatrix} = \begin{vmatrix} 3 \\ 2 \\ 1 \\ 1 \end{vmatrix}$$

$$B' = \begin{vmatrix} 1 & 0 & 0 & 2 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & -2 \\ 0 & 0 & 0 & 1 \end{vmatrix} \begin{vmatrix} -4 \\ 2 \\ -1 \\ 1 \end{vmatrix} = \begin{vmatrix} -2 \\ 2 \\ -3 \\ 1 \end{vmatrix}$$

Scaling

Scaling modifies the size of an object, while maintaining constant its position and its orientation.

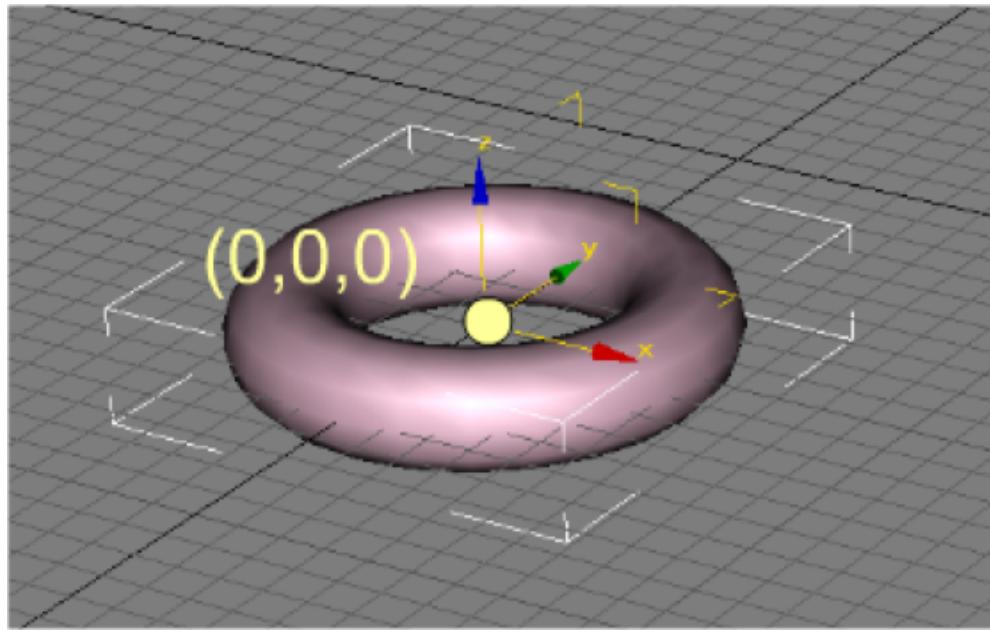

Scaling can be used to obtain several effects:

- Enlarge
- Shrink
- Deform
- Mirror
- Flatten

Scaling

The scale transforms have a center: a point that is not moved during the transformation.

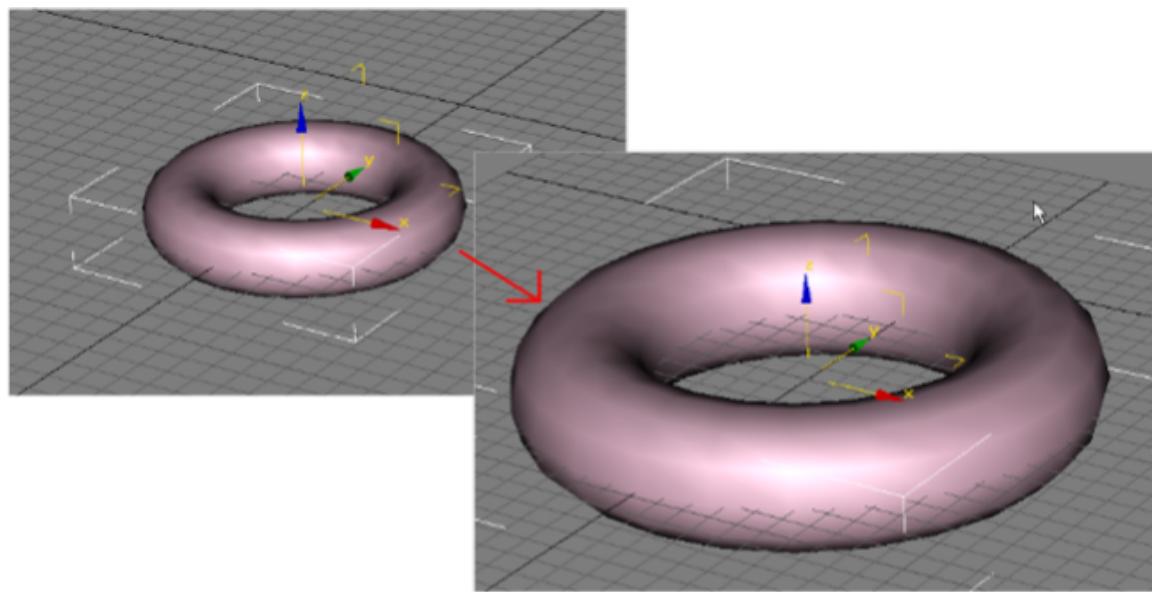

Initially, we consider the center of the scaling located in the origin of the 3D space.

Scaling

Proportional scaling enlarges or shrinks an object of the same amount s in all the directions.

For this reason proportional scaling maintains the proportions of the objects while changing its size.

Scaling

Multiplying the three coordinates of the points with a factor s performs proportional scaling.

$$x' = s \cdot x$$

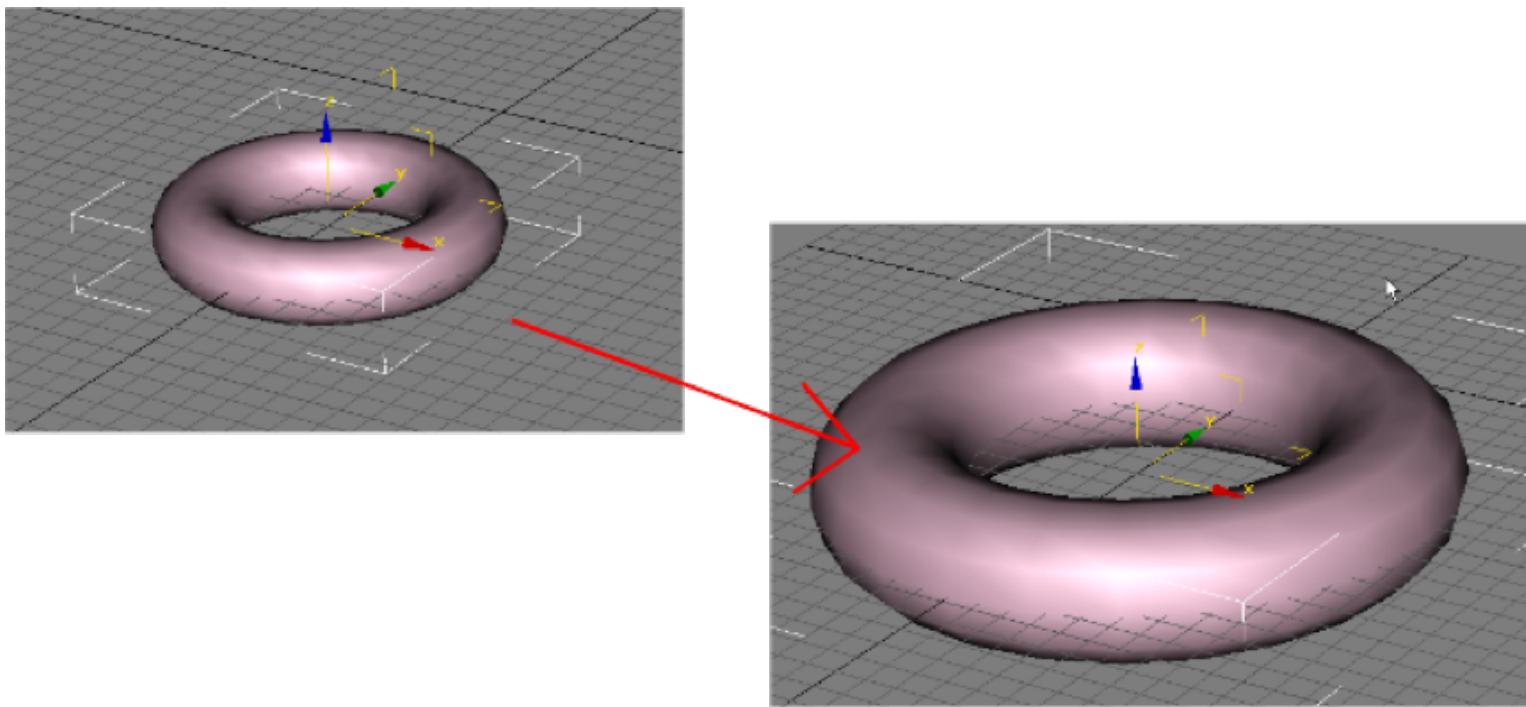

$$y' = s \cdot y$$

$$z' = s \cdot z$$

Depending on the value of s , the transformation can either enlarge or shrink an object.

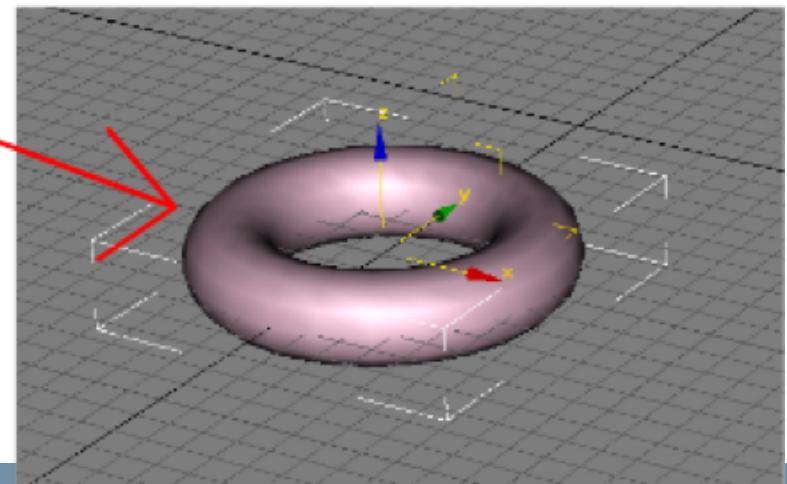

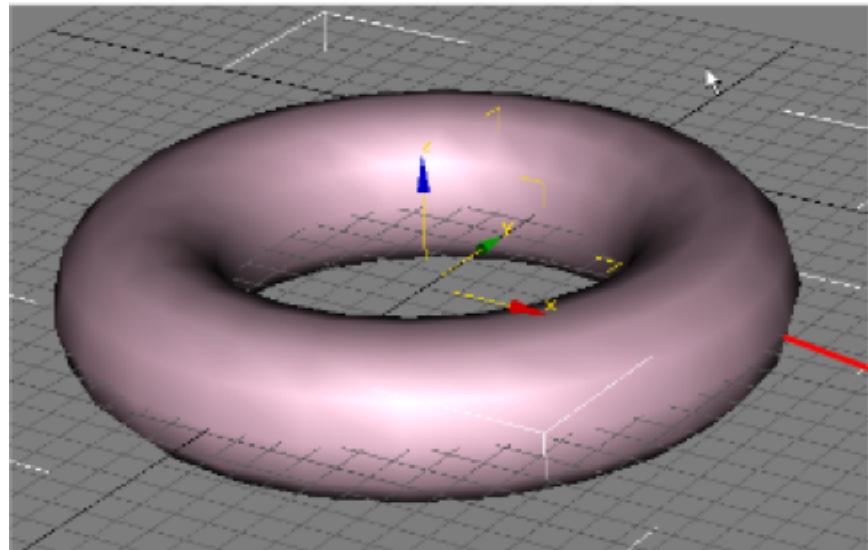

Scaling

A factor $s > 1$, enlarges s times the object. For example, $s=2$ doubles the size.

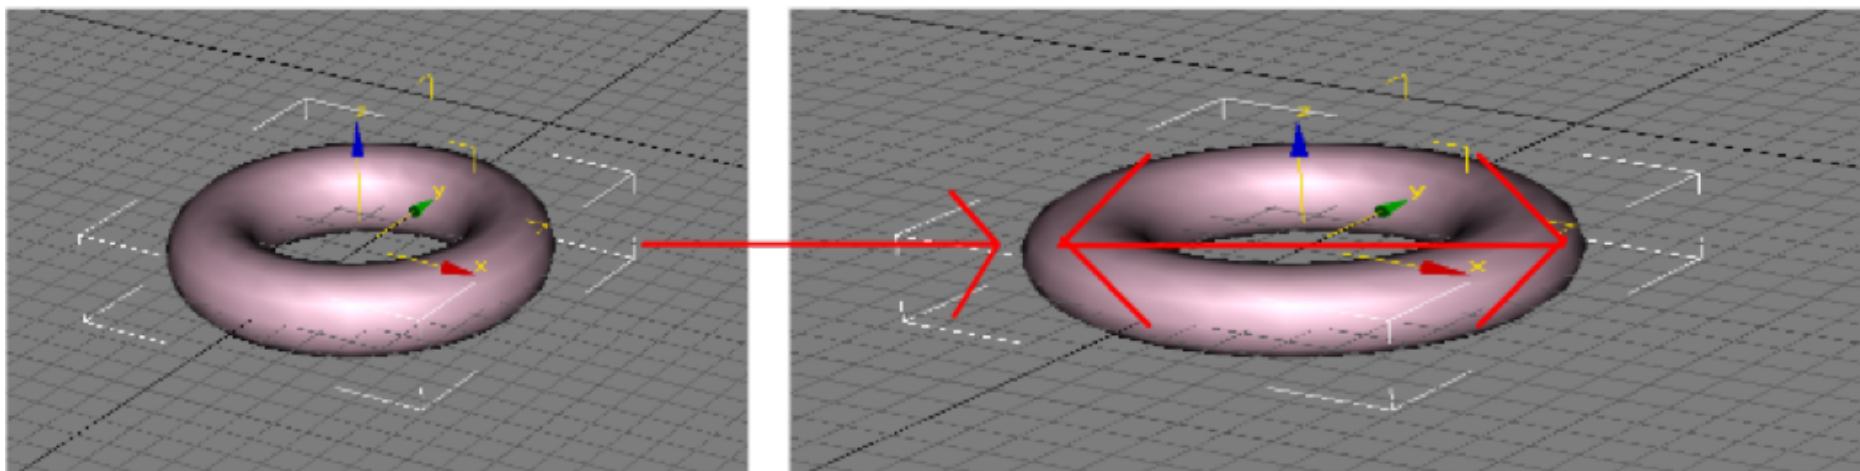

Scaling

A factor $0 < s < 1$, shrinks $1/s$ times the object. For example, $s=1/2=0.5$ halves the object.

Scaling

Non-proportional scaling deforms an object by using a different scaling factors s_x , s_y and s_z for each axis. It can be used to enlarge or shrink an object only in one direction.

Initially we will suppose that non-proportional scaling can only occur with respect to the three main axis. Later we will see how to apply non-proportional scaling in arbitrary directions.

Scaling

The new coordinates can be simply computed as:

$$x' = s_x \cdot x$$

$$y' = s_y \cdot y$$

$$z' = s_z \cdot z$$

The transform matrix $S(s_x, s_y, s_z)$ that performs scaling can be written by placing the scaling factors s_x , s_y and s_z on the diagonal:

$$S(s_x, s_y, s_z) = \begin{vmatrix} s_x & 0 & 0 & 0 \\ 0 & s_y & 0 & 0 \\ 0 & 0 & s_z & 0 \\ 0 & 0 & 0 & 1 \end{vmatrix}$$

Scaling

Example:

A scaling of 2.5 on the y-axis and 0.5 on z-axis is performed by matrix $S(1, 2.5, 0.5)$, and it can be used in the following way to transform points $A(1, 2, 3)$, $B(-4, 2, -1)$.

$$S(1, 2.5, 0.5) = \begin{vmatrix} 1 & 0 & 0 & 0 \\ 0 & 2.5 & 0 & 0 \\ 0 & 0 & 0.5 & 0 \\ 0 & 0 & 0 & 1 \end{vmatrix}$$
$$A' = \left| \begin{array}{cccc|c|c} 1 & 0 & 0 & 0 & 1 & 1 \\ 0 & 2.5 & 0 & 0 & 2 & 5 \\ 0 & 0 & 0.5 & 0 & 3 & 1.5 \\ 0 & 0 & 0 & 1 & 1 & 1 \end{array} \right|$$
$$B' = \left| \begin{array}{cccc|c|c} 1 & 0 & 0 & 0 & -4 & -4 \\ 0 & 2.5 & 0 & 0 & 2 & 5 \\ 0 & 0 & 0.5 & 0 & -1 & -0.5 \\ 0 & 0 & 0 & 1 & 1 & 1 \end{array} \right|$$

Scaling - mirroring

Mirroring can be obtained by *using negative scaling factors*.

In particular, three possible types of mirroring can be done:

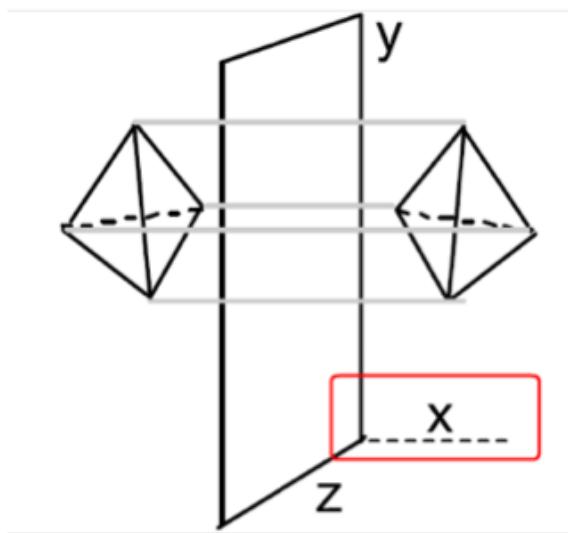

- Planar
- Axial
- Central

Again, we will initially assume that mirrors occurs around a plane, axis or center that passes through the origin and is aligned to the x , y or z axes.

Scaling - mirroring

Planar mirroring creates the symmetric object with respect to a plane.

It is obtained by assigning -1 to the scaling factor of the axis perpendicular to the plane (x for plane yz).

$$s_x = -1$$

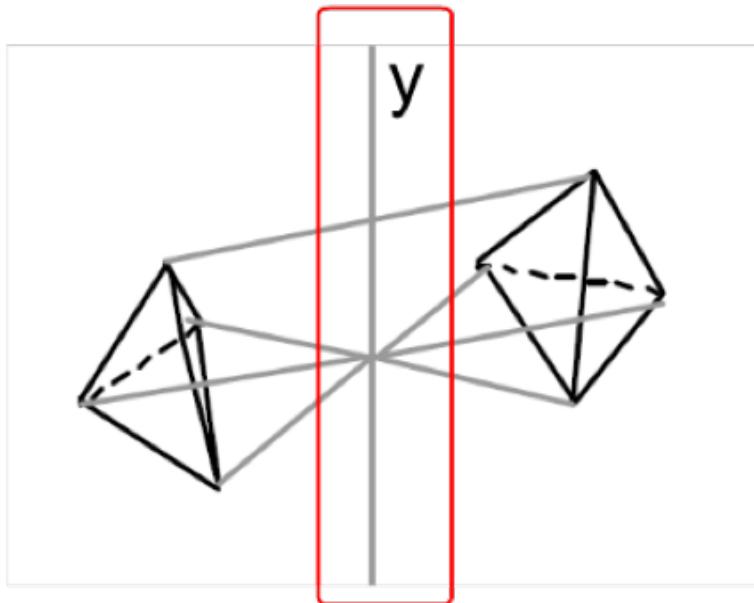

$$s_y = 1$$

$$s_z = 1$$

Scaling - mirroring

Axial mirroring creates the symmetric object with respect to an axis.

It is obtained by assigning -1 to all the scaling factors but the one of the axis (x and z for y-axis).

$$s_x = -1$$

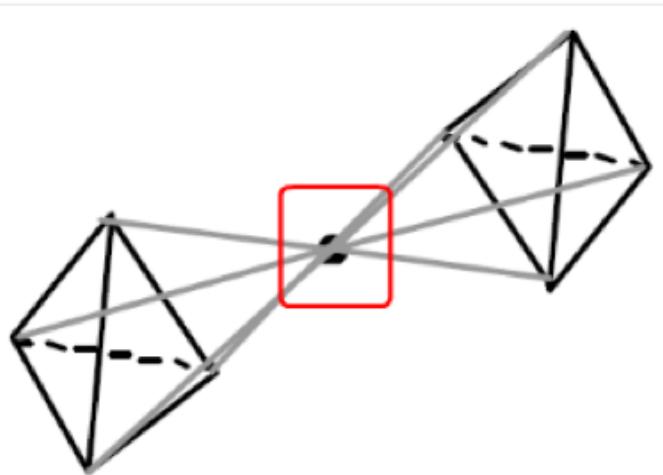

$$s_y = 1$$

$$s_z = -1$$

Scaling - mirroring

Central mirroring creates the symmetric object with respect to the origin.

It is obtained by assigning -1 to all the scaling factors.

$$s_x = -1$$

$$s_y = -1$$

$$s_z = -1$$

Scaling - flattening

A scaling factor of 0 in any direction, flattens the image along that axis. This however makes the transform matrix not invertible, a feature that might require special handling.

To simplify our discussion, we will almost always suppose that the scaling coefficients are different from 0.

$$x' = s_x \cdot x \quad s_x \neq 0$$

$$y' = s_y \cdot y \quad s_y \neq 0$$

$$z' = s_z \cdot z \quad s_z \neq 0$$

Scaling

Example:

Consider mirroring about the xy -plane.

The corresponding transform matrix is $S(1,1,-1)$, and it can be used to transform points $A(1, 2, 3)$, $B(-4, 2, -1)$ in the following way:

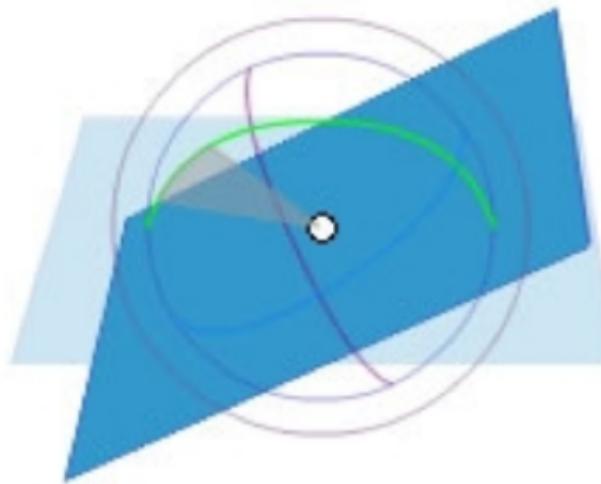

$$S(1,1,-1) = \begin{vmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 1 \end{vmatrix}$$

$$A' = \begin{vmatrix} 1 & 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 & 2 \\ 0 & 0 & -1 & 0 & 3 \\ 0 & 0 & 0 & 1 & 1 \end{vmatrix} = \begin{vmatrix} 1 \\ 2 \\ -3 \\ 1 \end{vmatrix}$$

$$B' = \begin{vmatrix} 1 & 0 & 0 & 0 & -4 \\ 0 & 1 & 0 & 0 & 2 \\ 0 & 0 & -1 & 0 & -1 \\ 0 & 0 & 0 & 1 & 1 \end{vmatrix} = \begin{vmatrix} -4 \\ 2 \\ 1 \\ 1 \end{vmatrix}$$

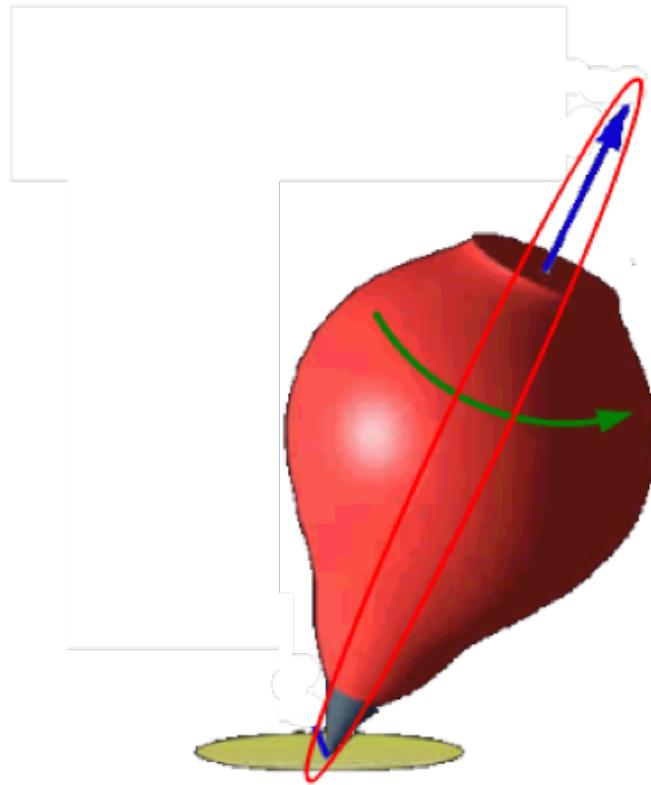

Rotation

Rotation varies the *orientation* of an object, leaving its position and size unchanged.

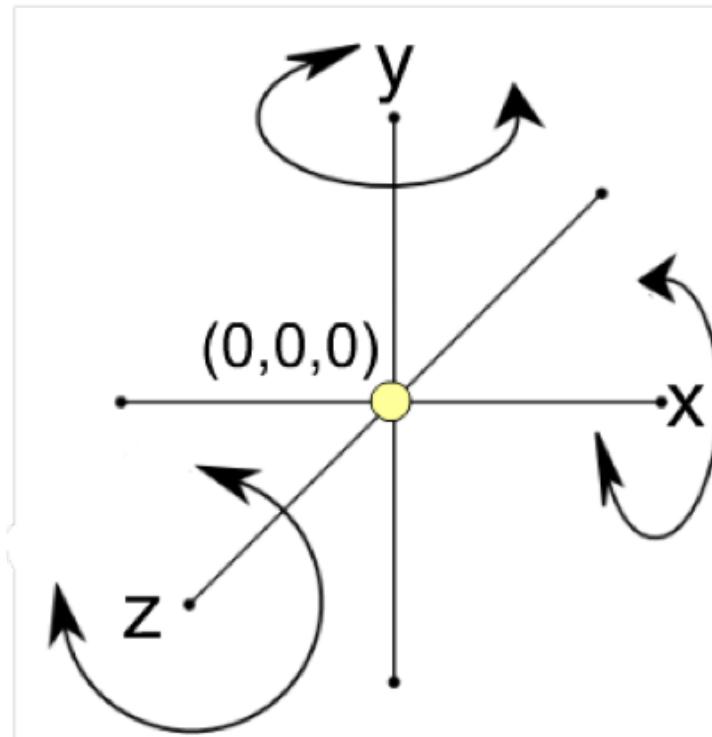

Rotation

Rotation is always performed along an *axis*: a line where points are unaffected by the transformation.

Rotation

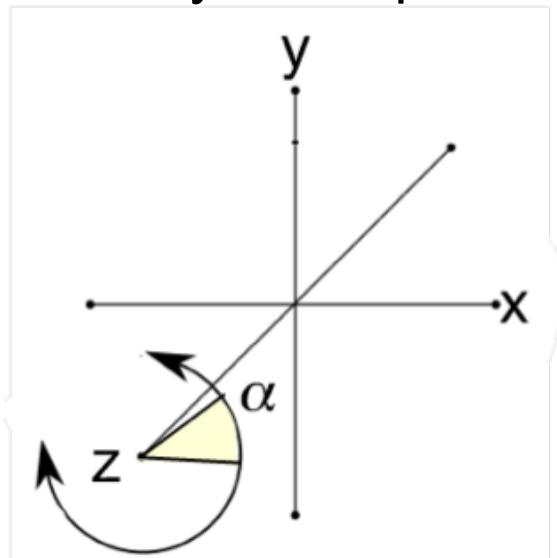

Even if rotations about arbitrary axis are possible, we will begin by considering only rotations about the three reference axis and passing through the origin.

Rotation

A rotation of an angle α about the z-axis can be computed as shown below. Note that points on the z-axis are unaffected.

A simple way to recall this formula is to first rotate the x component as if it was a point on the x-axis (i.e with $y=0$), then rotate the y component as a point on the y-axis (i.e with $x=0$) and finally sum up the two.

$$x' = x \cdot \cos \alpha - y \cdot \sin \alpha$$

$$y' = x \cdot \sin \alpha + y \cdot \cos \alpha$$

$$z' = z$$

Rotation

Similarly, the equations for the rotations among the other axis can be computed as:

x-axis

$$x' = x$$

$$y' = y \cdot \cos \alpha - z \cdot \sin \alpha$$

$$z' = y \cdot \sin \alpha + z \cdot \cos \alpha$$

y-axis

$$x' = x \cdot \cos \alpha + z \cdot \sin \alpha$$

$$y' = y$$

$$z' = -x \cdot \sin \alpha + z \cdot \cos \alpha$$

z-axis

$$x' = x \cdot \cos \alpha - y \cdot \sin \alpha$$

$$y' = x \cdot \sin \alpha + y \cdot \cos \alpha$$

$$z' = z$$

Rotation

Thanks to homogeneous coordinates, the following transform matrices express the rotations of an angle α around the corresponding axis:

X-axis

$$R_x(\alpha) = \begin{vmatrix} 1 & 0 & 0 & 0 \\ 0 & \cos \alpha & -\sin \alpha & 0 \\ 0 & \sin \alpha & \cos \alpha & 0 \\ 0 & 0 & 0 & 1 \end{vmatrix}$$

y-axis

$$R_y(\alpha) = \begin{vmatrix} \cos \alpha & 0 & \sin \alpha & 0 \\ 0 & 1 & 0 & 0 \\ -\sin \alpha & 0 & \cos \alpha & 0 \\ 0 & 0 & 0 & 1 \end{vmatrix}$$

z-axis

$$R_z(\alpha) = \begin{vmatrix} \cos \alpha & -\sin \alpha & 0 & 0 \\ \sin \alpha & \cos \alpha & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{vmatrix}$$

Rotation

Example:

Consider rotation of 90° on the y-axis. The corresponding matrix $R_y(90^\circ)$ is written as follows, and can be used to transform points A(1, 2, 3), B(-4, 2, -1) as shown.

$$R_y(90^\circ) = \left| \begin{array}{cccc} 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{array} \right|$$

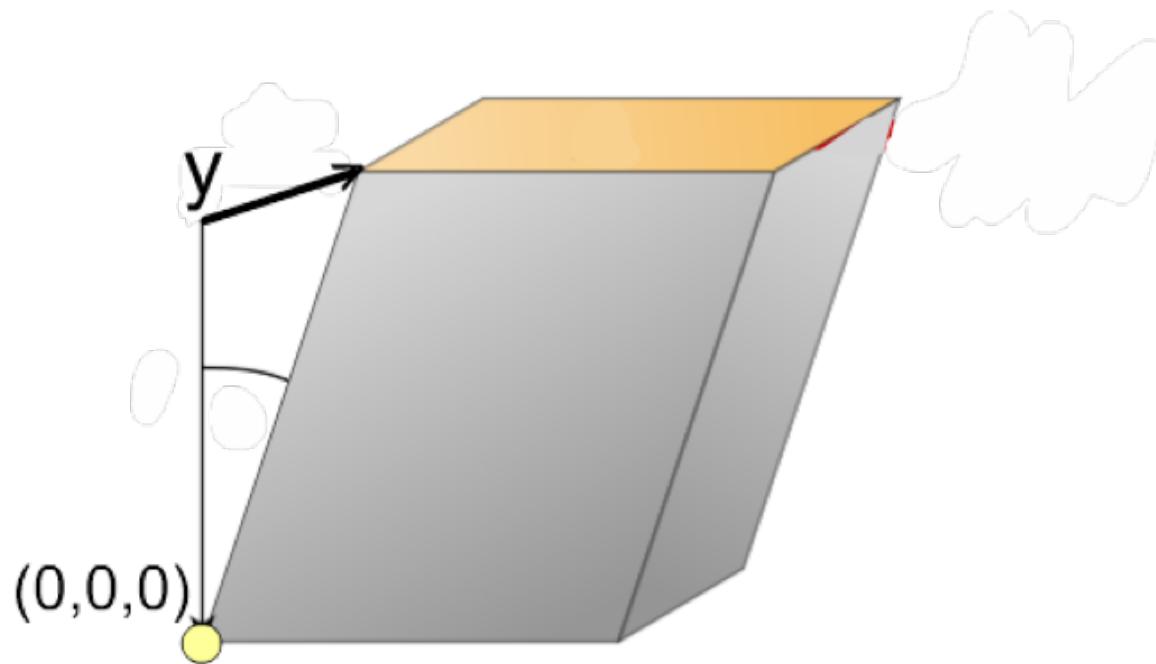

$$A' = \left| \begin{array}{cccc} 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{array} \middle| \begin{array}{c} 1 \\ 2 \\ 3 \\ 1 \end{array} \right| = \left| \begin{array}{c} 3 \\ 2 \\ -1 \\ 1 \end{array} \right|$$

$$B' = \left| \begin{array}{cccc} 0 & 0 & 1 & 0 \\ 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{array} \middle| \begin{array}{c} -4 \\ 2 \\ -1 \\ 1 \end{array} \right| = \left| \begin{array}{c} -1 \\ 2 \\ 4 \\ 1 \end{array} \right|$$

Shear

The **shear** transform *bends* an object in one direction.

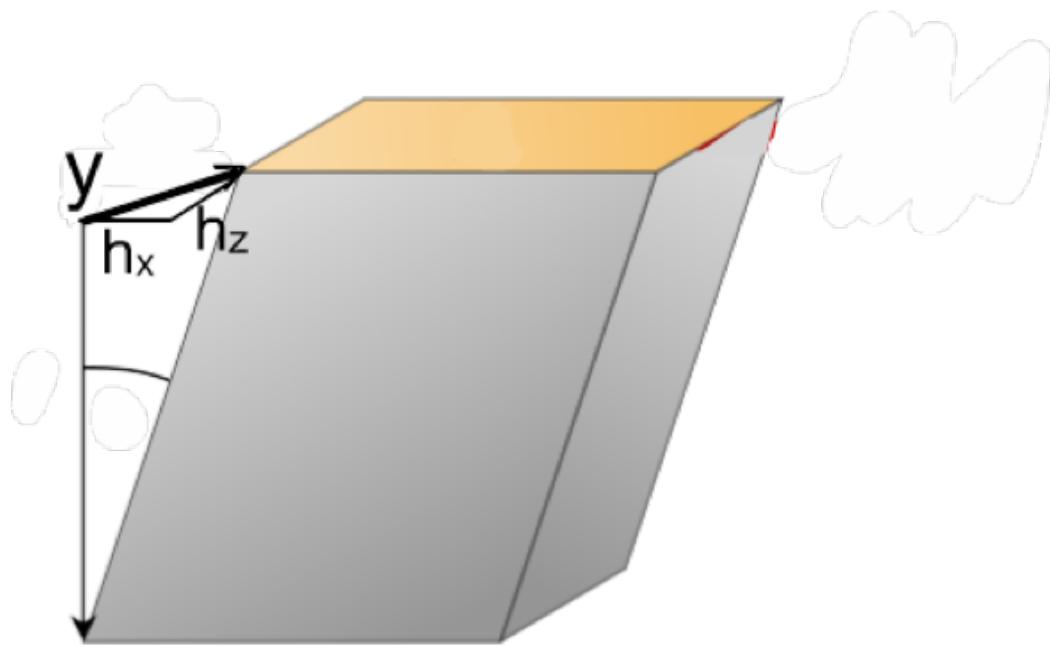

Shear is performed along an axis and has a center. We initially focus on the y-axis passing through the origin.

Shear

As the value of y-axis increases, the object is linearly bent into a direction specified by a vector (in this case defined by two values: h_x and h_z).

The coordinates of the transformed point can be computed as shown:

$$x' = x + y \cdot h_x$$

$$y' = y$$

$$z' = z + y \cdot h_z$$

Shear

The equations for the shear along all the axes are the following:

x-axis

$$\begin{aligned}x' &= x \\y' &= y + x \cdot h_y \\z' &= z + x \cdot h_z\end{aligned}$$

y-axis

$$\begin{aligned}x' &= x + y \cdot h_x \\y' &= y \\z' &= z + y \cdot h_z\end{aligned}$$

z-axis

$$\begin{aligned}x' &= x + z \cdot h_x \\y' &= x + z \cdot h_y \\z' &= z\end{aligned}$$

Shear

And the matrix formulations are:

x-axis

$$H_x(h_y, h_z) = \begin{vmatrix} 1 & 0 & 0 & 0 \\ h_y & 1 & 0 & 0 \\ h_z & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{vmatrix}$$

y-axis

$$H_y(h_x, h_z) = \begin{vmatrix} 1 & h_x & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & h_z & 1 & 0 \\ 0 & 0 & 0 & 1 \end{vmatrix}$$

z-axis

$$H_z(h_x, h_y) = \begin{vmatrix} 1 & 0 & h_x & 0 \\ 0 & 1 & h_y & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{vmatrix}$$

Shear

Example:

In the following you can see matrix $H_x(1, 0.5)$ that performs a shear along the x-axis which bends the object at the rate of 1 on the y-axis and 0.5 on z-axis. The matrix is used to transform points A(1, 2, 3), B(-4, 2, -1) .

$$H_x(1, 0.5) = \begin{vmatrix} 1 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 \\ 0.5 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{vmatrix}$$

$$A' = \begin{vmatrix} 1 & 0 & 0 & 0 & | & 1 & | & 1 \\ 1 & 1 & 0 & 0 & | & 2 & | & 3 \\ 0.5 & 0 & 1 & 0 & | & 3 & | & 3.5 \\ 0 & 0 & 0 & 1 & | & 1 & | & 1 \end{vmatrix}$$

$$B' = \begin{vmatrix} 1 & 0 & 0 & 0 & | & -4 & | & -4 \\ 1 & 1 & 0 & 0 & | & 2 & | & -2 \\ 0.5 & 0 & 1 & 0 & | & -1 & | & -3 \\ 0 & 0 & 0 & 1 & | & 1 & | & 1 \end{vmatrix}$$

Matrix transformations

Note that the last row in all the 4x4 transformation matrices is always $| 0 \ 0 \ 0 \ 1 |$.

This ensures that the w coordinate is unchanged by the transformation (and in particular it is kept $w=1$).

$$M = \begin{vmatrix} n_{xx} & n_{yx} & n_{zx} & d_x \\ n_{xy} & n_{yy} & n_{zy} & d_y \\ n_{xz} & n_{yz} & n_{zz} & d_z \\ 0 & 0 & 0 & 1 \end{vmatrix}$$

$p = (x, y, z, 1)$
 $p' = M \cdot p$
 $p' = (x', y', z', 1)$

Matrix transformations

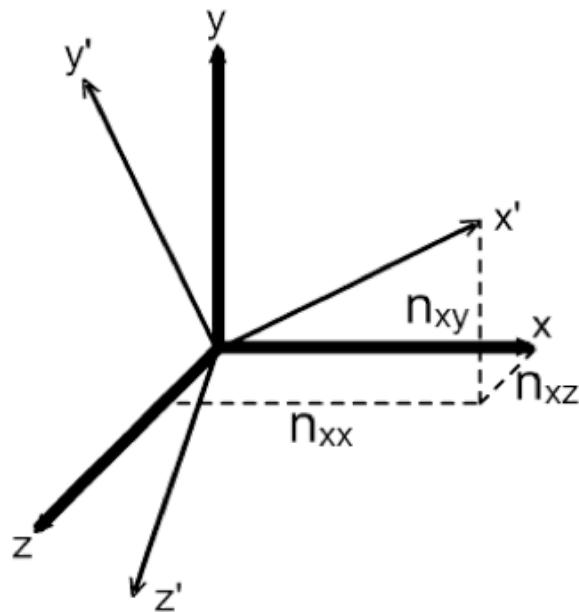

The upper part of a transform matrix, can be divided into a 3x3 sub-matrix \mathbf{M}_R that represents the rotation, scaling and shear factors of the transform, and a column vector \mathbf{d}^T that encodes the translation.

$$M = \begin{vmatrix} n_{xx} & n_{yx} & n_{zx} & | & d_x \\ n_{xy} & n_{yy} & n_{zy} & | & d_y \\ n_{xz} & n_{yz} & n_{zz} & | & d_z \\ \hline 0 & 0 & 0 & | & 1 \end{vmatrix} = \begin{vmatrix} M_R & | & \mathbf{d}^T \\ \hline \mathbf{0} & | & 1 \end{vmatrix}$$

Matrix transformations

In particular, the matrix product exchanges the three Cartesian axis of the original coordinate system, with three new directions.

The columns of \mathbf{M}_R represent the directions and sizes of the new axes in the old reference system (when translated to the origin).

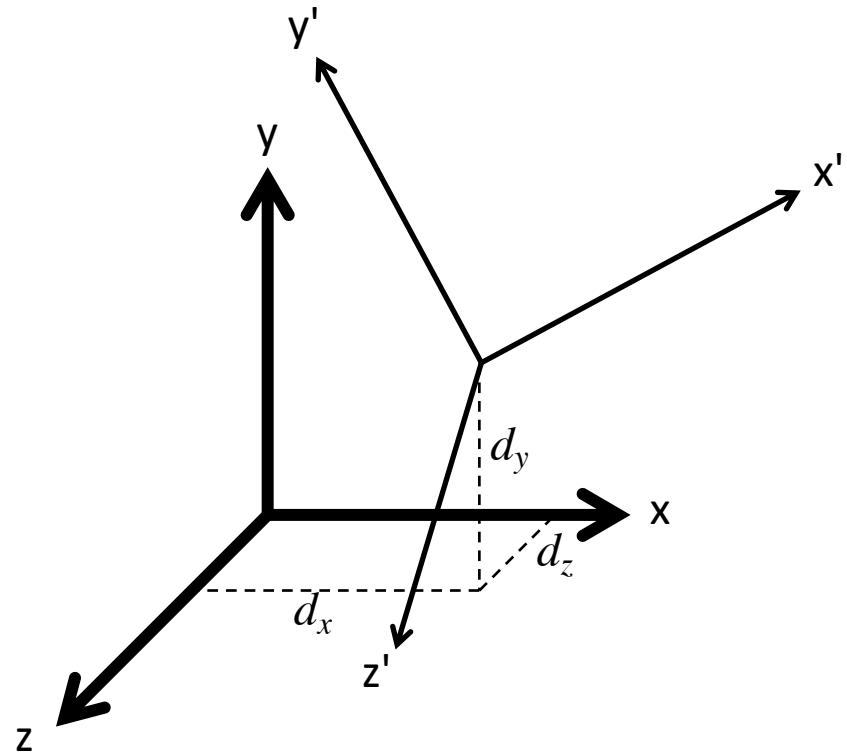

$$M_R = \begin{vmatrix} n_{xx} & n_{yx} & n_{zx} \\ n_{xy} & n_{yy} & n_{zy} \\ n_{xz} & n_{yz} & n_{zz} \end{vmatrix}$$

Matrix transformations

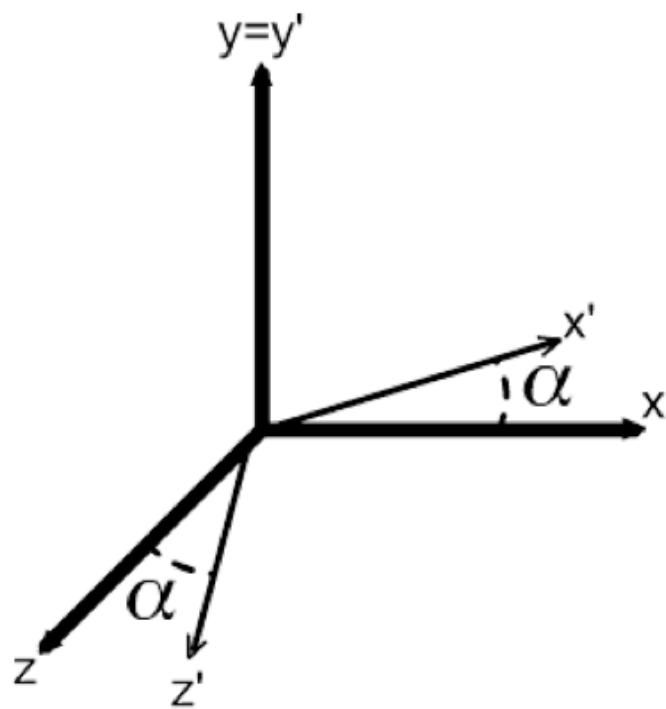

Vector \mathbf{d}^T represents the position of the origin of the new coordinates system in the old one.

$$M = \begin{vmatrix} M_R & \boxed{\begin{matrix} d_x \\ d_y \\ d_z \end{matrix}} \\ \hline 0 & 1 \end{vmatrix}$$

Matrix transformations

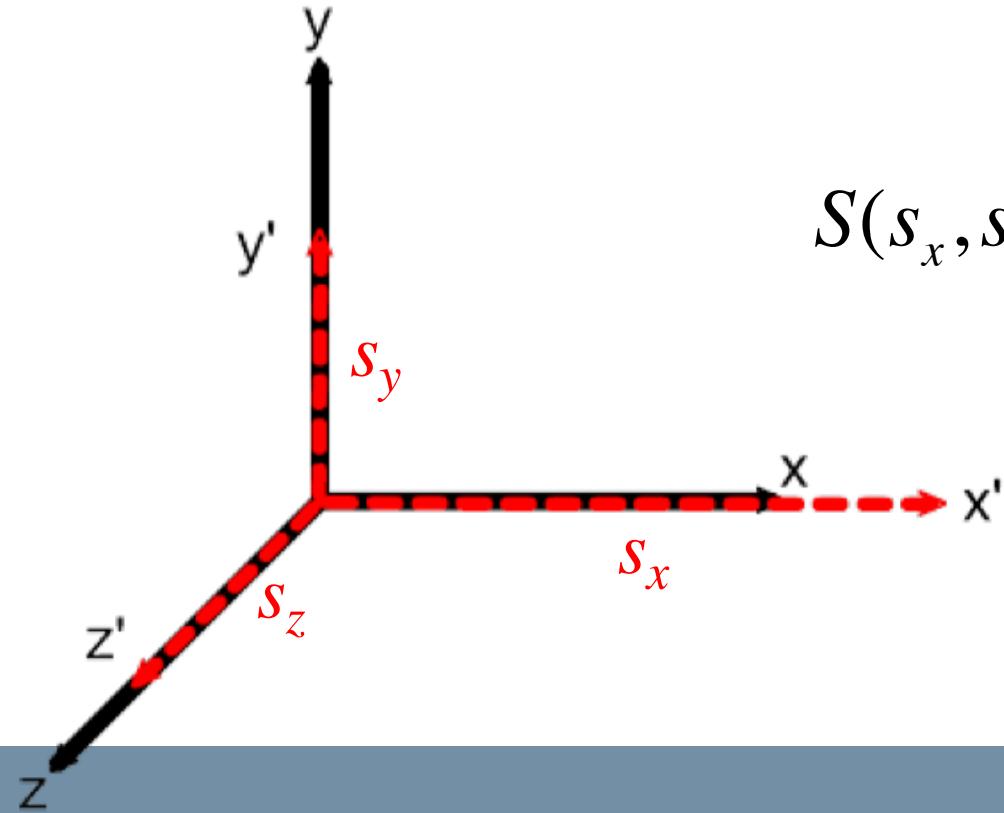

Rotations maintain the size and the angles of the axes constant, but change their directions.

$$R_y(\alpha) = \begin{vmatrix} \cos \alpha & 0 & \sin \alpha & 0 \\ 0 & 1 & 0 & 0 \\ -\sin \alpha & 0 & \cos \alpha & 0 \\ 0 & 0 & 0 & 1 \end{vmatrix}$$

Matrix transformations

Scaling increases or decreases the size of the axis, while maintaining their original directions.

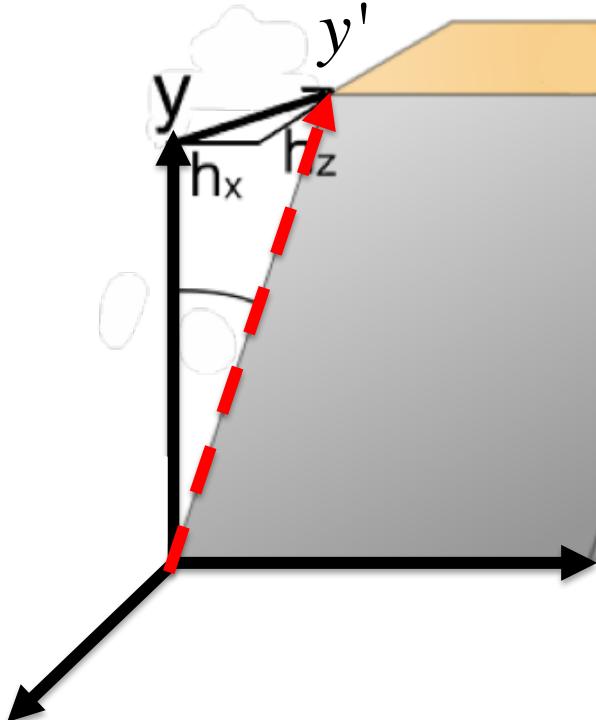

$$S(s_x, s_y, s_z) =$$

$$\begin{vmatrix} s_x & 0 & 0 & 0 \\ 0 & s_y & 0 & 0 \\ 0 & 0 & s_z & 0 \\ 0 & 0 & 0 & 1 \end{vmatrix}$$

Matrix transformations

Shear bends the axes.

$$H_y(h_x, h_z) = \begin{vmatrix} 1 & h_x & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & h_z & 1 & 0 \\ 0 & 0 & 0 & 1 \end{vmatrix}$$

Matrix transformations

Note that with the matrix-on-the-right convention, all the transform matrices are transposed.

$$M^T = \begin{vmatrix} n_{xx} & n_{xy} & n_{xz} & 0 \\ n_{yz} & n_{yy} & n_{yz} & 0 \\ n_{zx} & n_{zy} & n_{zz} & 0 \\ d_x & d_y & d_z & 1 \end{vmatrix} = \begin{vmatrix} M_R^T & \mathbf{0} \\ \mathbf{d} & 1 \end{vmatrix}$$

In this course, we will never use the matrix-on-the-right notation.

Matrix transformations

A way to determine which convention is used (if unknown), is by looking at a non-zero translation transform: if the matrix has the last *column* $|0\ 0\ 0\ 1|$, then matrix-on-the-right is used.

If the last *row* is $|0\ 0\ 0\ 1|$, then it is matrix-on-the-left (the one considered here).

Matrix-on-the-left

$$M = \left| \begin{array}{ccc|c} n_{xx} & n_{yx} & n_{zx} & d_x \\ n_{xy} & n_{yy} & n_{zy} & d_y \\ n_{xz} & n_{yz} & n_{zz} & d_z \\ \hline 0 & 0 & 0 & 1 \end{array} \right| = \left| \begin{array}{c|c} M_R & \mathbf{d}^T \\ \hline \mathbf{0} & 1 \end{array} \right|$$

In this course, we will never use the matrix-on-the-right convention.

Matrix-on-the-right

$$M^T = \left| \begin{array}{ccc|c} n_{xx} & n_{xy} & n_{xz} & 0 \\ n_{yz} & n_{yy} & n_{yz} & 0 \\ n_{zx} & n_{zy} & n_{zz} & 0 \\ \hline d_x & d_y & d_z & 1 \end{array} \right| = \left| \begin{array}{c|c} M_R^T & \mathbf{0} \\ \hline \mathbf{d} & 1 \end{array} \right|$$
